# Project Summary

## Project Scope

Project Name	Review Commit	Fixes Initial Commit	Fixes Final Commit	Platform	Start Date	End Date
ETHFI smart-contracts	<a href="#">733b5f5</a>	<a href="#">67588052</a>	<a href="#">77381e3f2</a>	EVM	10/12/2025	13/01/2026

## Project Overview

This document describes the manual review of the live contract code for the **ETHFI smart-contracts** core repository.

The work was a 30 day effort undertaken between **10/12/2025** and **13/01/2026**

The following contract list is included in our scope:

- src/AssetRecovery.sol
- src/BucketRateLimiter.sol
- src/DepositAdapter.sol
- src/EETH.sol
- src/EtherFiAdmin.sol
- src/EtherFiNode.sol
- src/EtherFiNodesManager.sol
- src/EtherFiOracle.sol
- src/EtherFiRateLimiter.sol
- src/EtherFiRedemptionManager.sol
- src/EtherFiRestaker.sol
- src/EtherFiRewardsRouter.sol
- src/EtherFiTimelock.sol
- src/LiquidityPool.sol
- src/Liquifier.sol
- src/MembershipManager.sol

- src/MembershipNFT.sol
- src/RoleRegistry.sol
- src/StakingManager.sol
- src/TVLOracle.sol
- src/UUPSProxy.sol
- src/WeETH.sol
- src/WithdrawRequestNFT.sol
- src/helpers/AddressProvider.sol
- src/helpers/EtherFiOperationParameters.sol
- src/helpers/EtherFiViewer.sol
- src/helpers/WeETHWithdrawAdapter.sol
- src/libraries/DepositDataRootGenerator.sol
- src/libraries/GlobalIndexLibrary.sol

The team performed a manual audit of the deployed Solidity smart contracts. During the manual audit, the Certora team discovered bugs in the Solidity smart contracts code, as listed on the following pages.

## Threat Model

### Assets

- **Native ETH:** Held in Liquidity Pool, Restaker contracts, Staking Manager.
  - **Liquid Staking Tokens (eETH):** Represents user shares of the underlying ETH pool.
  - **External Assets (stETH, cbETH, wBETH):** Held by Restaker contracts for yield generation.
  - **Membership NFTs:** ERC1155 tokens representing user tiers and loyalty status.
  - **Abstract Value:** Loyalty Points, Tier Points, and accrued staking rewards.
  - **Validator Stakes:** 32+ ETH deposits locked on the Beacon Chain.
- 

### Actors

- **EtherFi Admin Roles:** Privileged roles capable of upgrades, parameter setting, pausing and handling a wide range of permissioned flows related to managing pooled assets
  - **Oracle:** Trusted entity responsible for reporting portfolio performance (rewards/slashing in EigenLayer strategies, Lido, etc.).
  - **User/Staker:** Participants depositing ETH and holding eETH or Membership NFTs.
  - **Node Operator:** Entities managing the validator infrastructure.
  - **External Protocols:** Lido and EigenLayer (dependencies for withdrawals and restaking).
- 

### Trust Assumptions

- **Admin Competence & Honesty:** Assumes admins will not misconfigure critical parameters.
  - **Oracle Reliability:** Relies on the Oracle to accurately report rewards and slashing without desynchronizing from the Admin contract.
  - **Event completeness:** Off-chain systems assume emitted events fully describe on-chain state
  - **Bounded data structures:** Assumes admin managed arrays will not grow unbounded
  - **External Protocol Availability:** Assumes Lido and EigenLayer protocols function within expected constraints (e.g., minimum withdrawal amounts).
-

## Attack Vectors

- **Denial of Service (DoS):**
  - **Donation Attacks:** Sending dust ETH to contracts to force accounting mismatches and revert withdrawals.
  - **Logic Bombs:** Exploiting array length mismatches or integer overflows (e.g., during negative rebases) to permanently halt reward distribution.
- **Yield Leakage & Theft:**
  - **Slashing Evasion:** Migrating legacy positions during a loss event to reset principal value.
  - **Rounding Exploits:** Manipulating withdrawal amounts to bypass rate limits or extract dust value due to floor rounding.
  - **Griefing:** Resetting reward accrual timestamps frequently to prevent other users from earning points.
- **State Corruption:**
  - **Protocol Desynchronization:** Modifying Oracle parameters without updating the Admin, breaking the reporting pipeline.
  - **Logic Mixing:** Conflating legacy (V0) and new (V1) storage layouts, leading to incorrect share calculations.
- **Safety Failure:**
  - **Broken Pausing:** Critical functions lacking the whenNotPaused modifier, rendering emergency stops ineffective.
  - **Reentrancy:** Exploiting NFT onReceived callbacks to manipulate state during minting.
- **Accounting & Reporting Failures:**
  - **TVL Corruption:** Underreporting protocol value by ignoring specific assets (e.g., cbETH) or failing to account for slashing penalties in pending redemptions, leading to incorrect share pricing.
  - **Casting Underflows:** Corrupting global TVL variables during negative rebases (slashing events) by unsafely casting negative signed integers to unsigned integers.
- **Lifecycle & Initialization Risks:**
  - **Re-initialization:** Lack of idempotency in upgrade initialization functions, allowing admins to accidentally execute them multiple times and overwrite critical system addresses.

## Protocol Overview

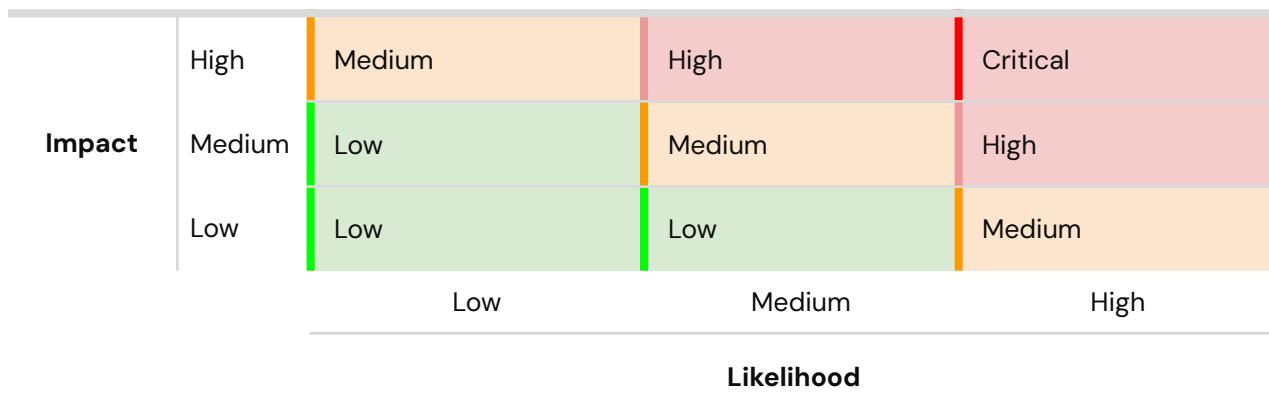

Ether.fi is a non-custodial liquid staking and restaking protocol where users deposit ETH to mint eETH, a rebasing ERC20 token that represents their share of the underlying staked assets and accrued rewards. The core architecture relies on a LiquidityPool contract that coordinates with a StakingManager to provision Ethereum validators, while an EtherFiOracle committee submits consensus layer reports to trigger rebasing and update the protocol's total value locked. A key differentiator is its deep integration with EigenLayer; the EtherFiNodesManager and EtherFiNode contracts facilitate native restaking by creating EigenPods, allowing validators to secure Actively Validated Services (AVS) for additional yield. The protocol also supports the intake and management of external Liquid Staking Tokens (LSTs) like stETH, which are managed and delegated via the EtherFiRestaker. Additionally, the system includes a loyalty layer managed by a MembershipManager, which tracks user engagement and distributes tier-based rewards via NFTs. Finally, the entire system is built on upgradeable UUPS proxy contracts, allowing for modular improvements to its staking, oracle, and node management logic.

## Findings Summary

The table below summarizes the findings of the review, including type and severity details.

Severity	Discovered	Confirmed	Fixed
Critical	-	-	-
High	-	-	-
Medium	8	8	2
Low	14	14	4
Informational	19	19	6
<b>Total</b>	<b>41</b>	<b>41</b>	<b>12</b>

## Severity Matrix

## Detailed Findings

ID	Title	Severity	Status
<a href="#">M-01</a>	Incorrect TVL Reporting in Liquifier & Restaker	Medium	Fixed
<a href="#">M-02</a>	Unbacked Shares Minted due to stETH Transfer Rounding	Medium	Fixed

<a href="#">L-14</a>	Treasury receives less than intended fee amount due to share value inflation after burning staker fee shares	Low	Fixed

## Medium Severity Issues

### M-01 Incorrect TVL Reporting in Liquifier & Restaker

Severity: Medium	Impact: High	Likelihood: Low
Files: <a href="#">Liquifier.sol</a>	Status: Fixed	

**Description:** The `Liquifier` contract contains view functions intended to report the Total Value Locked (TVL) and the distribution of assets (restaked, holding, pending withdrawals). Specifically, the `getTotalPooledEtherSplits` function relies on `tokenInfos[_token].strategyShare` and `tokenInfos[_token].ethAmountPendingForWithdrawals` to calculate the value of assets currently restaked in `EigenLayer` or pending withdrawal.

However, these fields (`strategyShare` and `ethAmountPendingForWithdrawals`) are never updated in the contract logic. The `depositWithERC20` function transfers assets to the `EtherFiRestaker` contract, but there is no callback or mechanism to update the Liquifier's state when those assets are deposited into a strategy or queued for withdrawal.

As a result, `getTotalPooledEther` will consistently report incorrect amounts for restaked tokens. If this function is used by off-chain oracles or front-ends to determine the protocol's exchange rate or health, it will lead to incorrect data, potentially causing share dilution or incorrect rebase rewards.

The same issue exists on the `EtherFiRestaker` contract, where the `getTotalPooledEther()` function (without arguments) calculates the total value held by the `EtherFiRestaker`. Currently, it only sums the `ETH balance` and the value of `Lido assets (stETH)`. However, the `Liquifier` contract deposits other tokens (like `cbETH`, `wBETH`) into `EtherFiRestaker`. These assets are completely ignored in this calculation. If this function is used to calculate the protocol's Total Value Locked (TVL) or exchange rates, it will underreport the value, leading to incorrect share pricing.

**Recommendations:** Implement a mechanism to synchronize the state between `EtherFiRestaker` and `Liquifier`, or refactor `Liquifier` to query `EtherFiRestaker` (or the underlying `EigenLayer` contracts) directly for the current state of restaked assets and pending withdrawals.

Inside `EtherFiRestaker` iterates through all supported tokens (transferred from `Liquifier` or a local list) and sums their values, similar to how `Liquifier.getTotalPooledEther()` attempts to do.

**Customer's response:** Fixed in commit [6423174](#)

**Fix Review:** Fixed

## M-02 Unbacked Shares Minted due to stETH Transfer Rounding

Severity: Medium	Impact: Medium	Likelihood: Medium
Files: <a href="#">Liquifier.sol</a>	Status: Fixed	

**Description:** When depositing stETH via `depositWithERC20`, the `Liquifier` contract transfers the specified `_amount` from the user to the `EtherFiRestaker` (or itself for L2). It then transfers the minted eETH shares based on this `_amount`.

However, stETH is known to [have a 1-2 wei rounding issue](#) where the amount actually received by the recipient can be slightly less than the amount requested in `transferFrom`. Because the `Liquifier` does not verify the actual amount received (by checking balances before and after the transfer), the protocol credits the user for the full `_amount` while receiving `_amount - (1-2) wei`.

Over time, this discrepancy creates a deficit in the protocol, leading to the minting of unbacked eETH shares.

**Recommendations:** Implement a "balance before" and "balance after" check to determine the actual amount of tokens received. Use this actual amount for the subsequent share calculation and minting logic.

**Customer's response:** Fixed in commit [f27ba44](#)

**Fix Review:** Fixed

### M-03 Critical State Corruption in `setPoints` due to VO/V1 Logic Conflict

Severity: Medium	Impact: High	Likelihood: Medium
Files:	Status:	
<a href="#">MembershipManager.sol</a>	Acknowledged	

**Description:** The `setPoints` function allows an admin to update points for a token. However, it inadvertently mixes VO and V1 logic in a way that corrupts the protocol's accounting.

1. It calls `_claimStakingRewards(_tokenId)`. For VO tokens, this function updates `tokenData[_tokenId].vaultShare` (slot 0) with `rewardsGlobalIndex`. This is legacy behavior where the first slot of `TokenData` was used for the rewards index.
2. It then calls `_claimTier(_tokenId)`. This function assumes V1 logic. It reads `tokenData[_tokenId].vaultShare` expecting it to be a "Vault Share" (amount of shares in the tier vault).
3. Instead, it reads the `rewardsGlobalIndex`. It then performs calculations using `eEthShareForVaultShare` and `vaultShareForEEthShare` based on this incorrect value.
4. Finally, it updates the global `tierVaults` accounting (`_decrementTierVaultV1` / `_incrementTierVaultV1`) using these bogus values.

This sequence corrupts the `tierVaults` state systemwide, permanently desynchronizing the total vault shares from the actual backing assets. This can lead to incorrect exchange rates for all users in those tiers.

**Recommendations:** Ensure the token is fully migrated to V1 before performing any V1-specific operations like `_claimTier`. Call `_migrateFromVOToV1(_tokenId)` explicitly in `setPoints` after claiming rewards and before claiming tier.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## M-04 Rewards Distribution for New Tiers(V1) could brake

Severity: Medium	Impact: High	Likelihood: Low
Files: <a href="#">MembershipManager.sol</a>	Status: Acknowledged	

**Description:** The `_distributeStakingRewardsV1` function iterates through tiers to update their share of rewards. However, the loop condition uses `tierDeposits.length`.

JavaScript

```
for (uint256 i = 0; i < tierDeposits.length; i++) {  
    tierVaults[i].totalPooledEEthShares = vaultTotalPooledEEthShares[i];  
}
```

`tierDeposits` is a legacy `VO` array. When new tiers are added via `addNewTier`, they are added to `tierData` and `tierVaults` (V1), but not to `tierDeposits`. Consequently, `tierDeposits.length` will be smaller than `tierVaults.length`. The loop will terminate early, and users in the newly added tiers will not receive any staking rewards updates.

**Recommendations:** Update the loop in `_distributeStakingRewardsV1` to iterate up to `tierVaults.length` or `tierData.length` instead of `tierDeposits.length`.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## M-05 Incorrect VO Rewards Calculation during Loss

Severity: Medium	Impact: High	Likelihood: Low
Files: <a href="#">MembershipManager.sol</a>	Status: Acknowledged	

**Description:** In `_distributeStakingRewardsVO`, the contract updates the shares associated with VO deposits:

JavaScript

```
tierDeposits[i].shares = uint128(liquidityPool.sharesForAmount(tierDeposits[i].amounts));
```

It uses `sharesForAmount` on the fixed ETH principal (`amounts`). If the pool suffers a loss (exchange rate drops), `sharesForAmount` increases. The contract then assumes it holds more shares than it actually does (since the actual shares held by `MembershipManager` in the LP did not increase).

This inflated share count is used to calculate the `globalIndex`. This can lead to incorrect reward distribution or accounting errors where the contract attempts to distribute rewards it does not possess.

**Recommendations:** The `VO` accounting logic relies on the assumption that `sharesForAmount` is stable or decreasing (appreciation). It is fundamentally incompatible with slashing/loss scenarios. Consider forcing migration to `V1` on all positions to make sure all reward distribution happens on the V1 branch.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## M-06 Rounding Issue in `_withdraw` allows value extraction

Severity: Medium	Impact: Medium	Likelihood: Medium
Files: <a href="#">MembershipManager.sol</a>	Status: Acknowledged	

**Description:** In the `_withdraw` function, the amount of vault shares to burn is calculated using `vaultShareForEthAmount`, which rounds down.

```
JavaScript
uint256 vaultShare = vaultShareForEthAmount(tier, _amount);
// ...
_decrementTokenVaultShareV1(_tokenId, vaultShare);
```

A user withdrawing `_amount` of `ETH` value will burn slightly fewer vault shares than mathematically required. They retain the "dust" shares in their `vaultShare` balance. Since `vaultShare` represents a claim on the pool, retaining these shares allows the user to potentially withdraw slightly more than they deposited over many transactions, or keeps the NFT "active" with a non-zero balance even after a full withdrawal.

**Recommendations:** Use a rounding-up mechanism (ceiling) when calculating the shares to burn for a given withdrawal amount to favor the protocol and prevent dust accumulation.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## M-07 Denial of Service in rebase due to Array Length Mismatch

Severity: Medium	Impact: High	Likelihood: Low
Files: <a href="#">GlobalIndexLibrary.sol</a>	Status: Acknowledged	

**Description:** The `calculateRewardsPerTierVO` function iterates through all tiers to calculate rewards. The loop limit is determined by `membershipManager.numberOfTiers()`, which returns the length of the `tierData` array (V1 storage).

However, inside the loop, the function accesses `membershipManager.tierDeposits(i)`. `tierDeposits` is a legacy VO array. When new tiers are added via `MembershipManager.addNewTier`, the function updates `tierData` and `tierVaults` but does not extend `tierDeposits`.

As a result, if any new tier is added, `numberOfTiers` will exceed the length of `tierDeposits`. When `calculateRewardsPerTierVO` attempts to access the index corresponding to the new tier in `tierDeposits`, the transaction will revert due to an array out-of-bounds error. Since this function is a critical component of the rebase workflow, adding a new tier will permanently break the protocol's ability to distribute rewards.

JavaScript

```
for (uint256 i = 0; i < numberOfTiers; i++) {
    //@audit-issue - if new tier is added, deposits array length will not grow and
    //cause a DOS on rebasing
    (uint128 amounts, uint128 shares) = membershipManager.tierDeposits(i);
```

**Recommendations:** Modify the loop in `calculateRewardsPerTierVO` to iterate only up to the length of `tierDeposits` (or a separate VO tier count), rather than `numberOfTiers` which reflects the

V1 state. Alternatively, ensure `tierDeposits` is resized when new tiers are added, even if unused by V1.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## M-08 Griefing Attack on Tier Points Accrual

Severity: Medium	Impact: Medium	Likelihood: Medium
Files: <a href="#">MembershipNFT.sol</a>	Status: Acknowledged	

**Description:** The `accruedTierPointsOf` function calculates the points earned since the last accrual timestamp. The formula divides the elapsed time by 1 days (86400 seconds) and multiplies by tierPointsPerDay (24).

JavaScript

```
uint256 earnedPoints = ((uint32(block.timestamp) - prevPointsAccrualTimestamp) *  
tierPointsPerDay) / 1 days;
```

This simplifies to  $\text{elapsed} / 3600$ . If the elapsed time is less than 3600 seconds (1 hour), the integer division results in 0.

The `MembershipManager.claim(uint256 _tokenId)` function is public and calls `_claimPoints`, which updates the `prevPointsAccrualTimestamp` to the current block timestamp.

A malicious actor can exploit this by calling `claim` on a victim's token ID every 59 minutes. This will repeatedly reset the `prevPointsAccrualTimestamp` while `earnedPoints` remains 0 due to rounding. As a result, the victim will not accrue any tier points, effectively denying them the benefits of their membership duration.

**Recommendations:** Update the `prevPointsAccrualTimestamp` only when at least 1 point is accrued. Alternatively, restrict the `claim` function so it can only be called by the token owner or approved operators, preventing third parties from resetting the accrual timer.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## Low Severity Issues

### L-01 Denial of Service in withdrawEther via Donation

Severity: <b>Low</b>	Impact: <b>Low</b>	Likelihood: <b>Low</b>
Files: <a href="#">Liquifier.sol</a>	Status: Fixed	

**Description:** The `withdrawEther` function allows an admin to sweep ETH held by the Liquifier contract back to the LiquidityPool. The function sends the entire balance of the Liquifier contract (`address(this).balance`) to the LiquidityPool.

In the `LiquidityPool.receive()` function, the received amount is subtracted from `totalValueOutOfLp`.

```
JavaScript
receive() external payable {
    if (msg.value > type(uint128).max) revert InvalidAmount();
    totalValueOutOfLp -= uint128(msg.value);
    totalValueInLp += uint128(msg.value);
}
```

`totalValueOutOfLp` tracks the amount of ETH that has left the pool (e.g., sent to Liquifier or validators). If the Liquifier contract holds more ETH than the LiquidityPool expects (i.e., `address(this).balance > totalValueOutOfLp`), the subtraction in LiquidityPool will underflow and revert.

This state might be reached if a malicious actor donates a small amount of ETH (dust) to the Liquifier contract, or if the Liquifier accumulates ETH from sources not accounted for in

`totalValueOutOfLp`. This effectively locks the ETH in the Liquifier contract as `withdrawEther` will always revert.

The issue also applies:

- to the `withdrawEther()` function inside `EtherFiRestaker`
- to the `withdrawToLiquidityPool()` function inside `EtherFiRewardsRouter`
- to the `completeQueuedETHWithdrawals()` function inside `EtherFiNode`

**Recommendations:** Modify `withdrawEther` to send the minimum of the contract's balance and the `LiquidityPool`'s `totalValueOutOfLp`.

**Customer's response:** Fixed in commit [08aa248](#)

**Fix Review:** Fixed – “Excess funds after `totalValueOutOfLp` may remain locked in EtherfiNode, EtherfiRewardRouter, EtherFiRestaker, and Liquifier and should be handled appropriately.”

## L-02 Missing Slashing Accounting in TVL Calculation

Severity: <b>Low</b>	Impact: <b>Low</b>	Likelihood: <b>Low</b>
Files: <a href="#">Liquifier.sol</a>	Status: Fixed	

**Description:** The `getTotalPooledEtherSplits` function calculates the value of restaked assets by directly converting the stored `strategyShare` to underlying tokens using `info.strategy.sharesToUnderlyingView`.

This approach is flawed for two reasons:

It relies on a static `strategyShare` variable stored in `Liquifier`, which does not reflect the actual state in `EigenLayer`.

Crucially, even if `strategyShare` were updated, this calculation fails to account for slashing. If the validator is slashed, the number of shares valid for withdrawal decreases.

The correct method to determine the value of restaked assets is to query the `EigenLayer DelegationManager` for `getWithdrawableShares`. This function returns the number of shares available to the staker, accounting for any slashing penalties that have occurred. Relying on the raw share count overestimates the protocol's TVL in the event of slashing.

**Recommendations:** Update the TVL calculation logic to query `DelegationManager.getWithdrawableShares(address(this), strategies)` to obtain the slashed-adjusted share amount before converting it to the underlying token amount.

**Customer's response:** Fixed in commit [6423174](#)

**Fix Review:** Fixed

### L-03 Incorrect Inclusion of Transferred Assets in TVL

Severity: Low	Impact: High	Likelihood: High
Files: <a href="#">Liquifier.sol</a>	Status: Fixed	

**Description:** The `getTotalPooledEther` function in `Liquifier.sol` attempts to calculate the total value of the protocol by summing up balances and "restaked" amounts calculated via `getTotalPooledEtherSplits`.

However, the `depositWithERC20` function transfers non-L2 tokens directly to the `EtherFiRestaker` contract:

Since the `Liquifier` contract does not hold these tokens and does not receive the strategy shares (which are minted to `EtherFiRestaker`), it is logically incorrect for `Liquifier` to attempt to report these as part of its own pooled Ether. The Liquifier has effectively become a pass-through for these assets, yet the view functions still attempt to perform accounting as if the assets were retained or tracked locally. This leads to confusion and potentially incorrect data if off-chain systems rely on `Liquifier.getTotalPooledEther`.

**Recommendations:** Remove the logic in `Liquifier` that attempts to calculate the value of assets held by `EtherFiRestaker` in case the `Liquifier` is not planned to hold restaked assets as well (which is not the case currently)

**Customer's response:** Fixed in commit [77381e3f](#)

**Fix Review:** Fixed

## L-04 Inaccurate TVL for Pending Redemptions due to Slashing

Severity: Low	Impact: Medium	Likelihood: Low
Files: <a href="#">EtherFiRestaker.sol</a>	Status: Acknowledged	

**Description:** The `getAmountPendingForRedemption` function calculates the value of `stETH` currently in the `Lido` withdrawal queue by summing the `amountOfStETH` of each request.

`amountOfStETH` represents the amount of tokens locked at the time of the request. It does not account for slashing penalties that may occur before finalization. If `Lido` validators are slashed, the actual `ETH` claimable for those shares will be lower than the original `amountOfStETH`. Using the face value of the locked tokens overestimates the protocol's assets in slashing scenarios.

**Recommendations:** Fixing this issue requires complicating the `getTotalPooledEther()` function to ensure proper reporting.

- For **unfinalized** requests, calculate the value based on the underlying shares and the current `Lido` exchange rate through `getPooledEthByShares()` (which reflects the latest slashing index).
- For **finalized** requests, use the claimable `ETH` amount via `Lido getClaimableEther()`, which requires providing a `hint` as input. The mental model is as follows:

JavaScript

1. `if isFinalized -> getClaimableEther(reqId) -> this` requires the precise hint to be inputed  
-> after finalization amounts are not subject to slashing so `getPooledEthByShares()` would not work
2. `if NOT isFinalized -> lido.getPooledEthByShares(req.amountOfShares) -> latest slashing`

**Customer's response:** Acknowledged - “It’s a very unlikely scenario that `Lido`’s `stETH` gets slashed.”

**Fix Review:** Acknowledged

## L-05 Loss Avoidance during VO to V1 Migration

Severity: <b>Low</b>	Impact: <b>Medium</b>	Likelihood: <b>Low</b>
Files: <a href="#">MembershipManager.sol</a>	Status: Acknowledged	

**Description:** The `_migrateFromVOToV1` function calculates the new V1 position based on the raw ETH principal amount recorded in VO (`tokenDeposits[_tokenId].amounts`). It does not account for potential losses (slashing) that may have occurred in the underlying Liquidity Pool.

```
JavaScript
uint128 amount = tokenDeposits[_tokenId].amounts;
// ...
uint256 eEthShare = liquidityPool.sharesForAmount(amount);
```

If the Liquidity Pool has suffered a loss, `sharesForAmount(amount)` will return more shares than the user effectively holds. By minting these new shares in the V1 system, the user is credited with the full original ETH value, effectively escaping the slashing loss. This loss is transferred to the remaining stakers in the protocol.

**Recommendations:** The whole VO accounting follows this pattern of using the amounts, instead of the shares, so changing the logic here might be a very complicated effort, requiring changes throughout the whole contract.

The team should be aware of the behaviour in case of loss and potentially execute migration of all existing VO positions, to ensure there is no exposure to the above edge case.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## L-06 Re-initialization Risk in initializeOnUpgrade

Severity: Low	Impact: Medium	Likelihood: Low
Files: <a href="#">MembershipManager.sol</a> 1	Status: Acknowledged	

**Description:** The `initializeOnUpgrade` function sets important protocol parameters and addresses. While it is restricted to `onlyOwner`, it lacks a mechanism (like initializer or a boolean flag) to prevent it from being called multiple times. Accidental re-execution could overwrite the `etherFiAdmin` address or reset `fanBoostThreshold` and `burnFeeWaiverPeriodInDays` unexpectedly.

The same consideration applies to `initializeOnUpgrade` inside the `MembershipNFT` contract

**Recommendations:** Check that `etherFiAdmin` is not 0 to prevent secondary calls to the function.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## L-07 Zombie State Creation in claim

Severity: <b>Low</b>	Impact: <b>Low</b>	Likelihood: <b>Low</b>
Files: <a href="#"><u>MembershipManager.sol</u></a>	Status: Acknowledged	

**Description:** The `claim` function does not verify if the `tokenId` exists or has been burned. If called on a burned/non-minted token (where `tokenData` is 0), it will execute `_claimPoints`, which sets `token.prevPointsAccrualTimestamp` to the current block timestamp and also set `version` to 1.

This effectively resurrects a "zombie" state for a non-existent token. While `MembershipNFT` tracks ownership, this dirty state in `MembershipManager` could lead to confusion or logic errors if other functions rely on token data

**Recommendations:** Add a check `require(membershipNFT.exists(_tokenId))` or similar validation at the beginning of the `claim` function.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## L-08 rewardsGlobalIndex unnecessarily stored as vaultShares

Severity: Low	Impact: High	Likelihood: High
Files: <a href="#">MembershipManager.sol</a>	Status: Acknowledged	

**Description:** Upon migration the `token.vaultShare` variable is set to `rewardsGlobalIndex`, which immediately after that is overwritten with the V1 vault shares. Currently it makes sense to completely remove this legacy update to vault, since it never gets used (since v0 always migrates to v1 after that). This also reduces the attack surface of potential accounting discrepancies

```
JavaScript
token.vaultShare = tierData[tier].rewardsGlobalIndex;
```

**Recommendations:** Remove the line that updates `vaultShares` to `rewardsGlobalIndex`

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## L-09 Broken EAP Calculation for Bronze Tier

Severity: <b>Low</b>	Impact: <b>Low</b>	Likelihood: <b>Low</b>
Files: <a href="#">MembershipNFT.sol</a>	Status: Acknowledged	

**Description:** The `computeTierPointsForEap` function calculates points for **Early Adopter Pool (EAP)** users. It uses an array `lastBlockNumbers` where `lastBlockNumbers[0]` is explicitly set to 0.

If a user falls into the Bronze tier (`tierId = 0`), the code attempts to calculate the projection:

```
JavaScript
tierPoints += ((next - current) * (lastBlockNumbers[tierId] - _eapDepositBlockNumber)) / ...
```

Substituting `tierId = 0`:

```
JavaScript
(lastBlockNumbers[0] - _eapDepositBlockNumber) => (0 - _eapDepositBlockNumber)
```

Since `_eapDepositBlockNumber` is positive, this subtraction causes an integer underflow and reverts. This makes it impossible for any Bronze tier EAP user to migrate their points. Additionally, the denominator `lastBlockNumbers[tierId] - lastBlockNumbers[nextTierId]` would be 0 - 17664247, which also underflows.

**Recommendations:** Add a check to skip this calculation if `tierId == 0`, or adjust the logic to handle the Bronze tier correctly (likely by not projecting points backwards from block 0).

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## L-10 Reward index calculation does not factor losses for VO positions

Severity: <b>Low</b>	Impact: <b>Medium</b>	Likelihood: <b>Low</b>
Files: <a href="#">MembershipNFT.sol</a>	Status: Acknowledged	

**Description:** The `_VO_accruedStakingRewardsOf` function does not handle scenarios where the protocol suffers a loss (negative rebase).

While `MembershipNFT` handles the decrease by returning 0 rewards (if `(rewardsGlobalIndex > rewardsLocalIndex)`), in `GlobalIndexLibrary.calculateGlobalIndex`, when a loss occurs, the library subtracts from the global index:

```
JavaScript
if (isLoss) {
    globalIndex[i] -= uint96(delta);
}
```

This however does not get reflected in the VO position – for example when `_claimStakingRewards` is called `_incrementTokenDeposit` & `_incrementTierDeposit` will always retain the original amount and only increase it and when there are losses they will not get impacted. At the same time V1 positions will get their assets reduced, decreasing the amount of pooled shares.

**Recommendations:** The whole VO accounting follows this pattern of using the amounts, instead of the shares, so changing the logic here might be a very complicated effort, requiring changes throughout the whole contract.

The team should be aware of the behaviour in case of loss and potentially execute migration of all existing VO positions, to ensure there is no exposure to the above edge case.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## L-11 Hypothetical underflow risk in rebase during slashing events

Severity: <b>Low</b>	Impact: <b>Low</b>	Likelihood: <b>Low</b>
Files: <a href="#">LiquidityPool.sol</a>	Status: Acknowledged	

**Description:** The rebase function in `LiquidityPool` adjusts the protocol's Total Value Locked (TVL) by adding `_accruedRewards` to `totalValueOutOfLp`. This `_accruedRewards` value can be negative in the case of a slashing event. The current implementation performs the calculation `int128(totalValueOutOfLp) + _accruedRewards` and casts the result back to `uint128`.

If a slashing event occurs where the absolute value of the negative `_accruedRewards` is greater than the current `totalValueOutOfLp`, the result of the addition will be a negative number. Casting this negative number to an unsigned integer type (`uint128`) will cause it to underflow and wrap around to a very large positive value. This would permanently corrupt the `totalValueOutOfLp` accounting, breaking the protocol's TVL tracking and share price calculation.

Given the immense amount of funds accounted for in `totalValueOutOfLp` (in the billions) and the very low likelihood of slashing happening, the risk is very close to none. Still the impact of this edge case would be significant hence it makes sense to add a sanity check that would revert in case of underflow.

**Recommendations:** Make sure to check that `_accruedRewards` is never > `totalValueOutOfLp` and revert, which would give the team time to think how to handle the situation.

**Customer's response:** Acknowledged - *"It's very unlikely as mentioned, but important. So will include this check when moving the rebase logic from MembershipManager to LiquidityPool rather than making an upgrade just for the check."*

**Fix Review:** Acknowledged

## L-12 Protocol Desynchronization via setReportStartSlot

Severity: Low	Impact: Low	Likelihood: Low
Files: <a href="#">EtherFiOracle.sol</a>	Status: Acknowledged	

**Description:** The `EtherFiOracle` contract allows the admin to update the `reportStartSlot` via `setReportStartSlot`. This variable is used in `blockStampForNextReport` to determine the expected `slotFrom` for the next report if no reports have been published yet (`lastPublishedReportRefSlot == 0`).

However, the `EtherFiAdmin` contract calculates the expected start slot for processing (`slotForNextReportToProcess`) based solely on its own `lastHandledReportRefSlot`.

If `setReportStartSlot` is called to update the start slot (e.g., to skip slots or restart reporting), `EtherFiOracle` will generate reports with a `refSlotFrom` equal to the new `reportStartSlot`. `EtherFiAdmin`, expecting `lastHandledReportRefSlot + 1`, will reject these reports in `executeTasks` because the `refSlotFrom` does not match. This breaks the reporting pipeline, causing a Denial of Service.

**Recommendations:** Consider removing the `setReportStartSlot()` function from `EtherFiOracle`, since it makes sense to set the value of `startSlot` only once.

**Customer's response:** Acknowledged – “That function is access controlled and will most likely never be called. Acknowledging the issue and can implement it in the next contract upgrade.”

**Fix Review:** Acknowledged

### L-13 Broken Pausing Mechanism

Severity: <b>Low</b>	Impact: <b>Low</b>	Likelihood: <b>Low</b>
Files: <a href="#">StakingManager.sol</a>	Status: Acknowledged	

**Description:** The `StakingManager` contract implements `pauseContract` and `unPauseContract` functions and inherits from `PausableUpgradeable`. However, the `whenNotPaused` modifier is not applied to any function within the contract.

As result the `pausing()`/`unpausing()` in `EtherFiAdmin` will not pause anything in that contract.

**Recommendations:** Double check if any functions should be pausable inside the `StakingManager`

**Customer's response:** Acknowledged – “All functions are only called by `LiquidityPool` which has the `whenNotPaused` modifier. So, pausing `LiquidityPool`, pauses the functions. Other functions are access controlled by multisig so won’t be an issue.”

**Fix Review:** Acknowledged

### L-14 Treasury receives less than intended fee amount due to share value inflation after burning staker fee shares

Severity: Low	Impact: Low	Likelihood: Low
Files: <a href="#">EtherFiRedemptionManager.sol</a>	Status: Fixed	

**Description:** The `_calcRedemption` function in `EtherFiRedemptionManager` calculates the treasury fee amount(`eEthFeeAmountToTreasury`) before burning staker fee shares. When `feeShareToStakers` is burned, the total share supply decreases while total assets remain constant, causing the value per share to increase. This means `feeShareToTreasury` shares have more value after the burn than the pre calculated `eEthFeeAmountToTreasury`. However, the contract only transfers the pre calculated `eEthFeeAmountToTreasury` to the treasury, leaving the additional value stuck in the contract. This results in:

1. Treasury receiving less than their entitled fee amount
2. Value accumulating in the contract that should have been sent to the treasury
3. Potential loss of protocol revenue over time

**Recommendation:** There are two solutions:

1. Burn the shares after sending `eEthFeeAmountToTreasury` to the treasury.
2. Recalculate `eEthFeeAmountToTreasury` based on the updated ratio and `feeShareToTreasury`.

**Customer's response:** Fixed in commit [6758805](#)

**Fix Review:** Fixed

## Informational Issues

---

### I-01. Token Registration Bypass via updateWhitelistedToken in Liquifier

**Description:** The `depositWithERC20` function in `Liquifier` checks if a token is whitelisted using `isTokenWhitelisted`. However, it does not explicitly check if the token has been properly initialized via `registerToken`.

The `updateWhitelistedToken` function allows an admin to whitelist any address. If a supported token (like lido stETH) is whitelisted via this function without being registered first, the `tokenInfos` struct for that token will remain uninitialized (default values).

While deposits will succeed (as `quoteByMarketValue` handles hardcoded token addresses), critical configuration parameters set during registration—such as the EigenLayer strategy address—will be missing.

**Recommendation:** Ensure that `updateWhitelistedToken` can only be called on tokens that have been previously registered, or add a check in `depositWithERC20` to ensure the token's configuration (e.g., strategy address) is valid.

**Customer's response:** Acknowledged – “*We don't have any deposit tokens. It is intended to be used only for L2ETH. Hence, having a direct whitelisting is helpful.*”

**Fix Review:** Acknowledged

## I-02. Missing Events for State Changing Functions in Liquifier

**Description:** Most state-changing administrative functions in Liquifier.sol do not emit events. This includes `updateTimeBoundCapRefreshInterval`, `updateDiscountInBasisPoints`, `updateWhitelistedToken`, `updateDepositCap`, `registerToken` etc.. The lack of events makes it difficult for off-chain monitoring tools and indexers to track critical changes to the protocol configuration and asset movements.

**Recommendation:** Define and emit events for all state-changing functions.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

### I-03. Redundant and Broken Token Pause Mechanism

**Description:** The `pauseDeposits()` in `Liquifier` function allows an admin to "pause" deposits for a specific token by setting its deposit caps to zero. This is redundant because the `depositWithERC20` function is already protected by the `whenNotPaused` modifier, which enforces a global protocol pause.

**Recommendation:** Consider removing the redundant function

**Customer's response:** Fixed in commit [Ob9f275](#)

**Fix Review:** Fixed

## I-04. Revert in stEthRequestWithdrawal due to Small Remainder

**Description:** The `stEthRequestWithdrawal` function splits large stETH withdrawal requests into smaller chunks to respect Lido's `MAX_STETH_WITHDRAWAL_AMOUNT`. However, the logic does not ensure that the final chunk respects Lido's `MIN_STETH_WITHDRAWAL_AMOUNT`.

If the requested `_amount` is slightly larger than a multiple of `MAX_STETH_WITHDRAWAL_AMOUNT` (e.g., `MAX + 1` wei), the loop will create a final request for that small remainder (e.g., 1 wei). Lido's `requestWithdrawals` function reverts if any request amount is less than the minimum (typically small, but non-zero). This causes valid large withdrawal requests to fail.

**Recommendation:** Ensure the remainder is at least `MIN_STETH_WITHDRAWAL_AMOUNT`. If the remainder is too small, reduce the penultimate request slightly to increase the final request, or ensure `_amount` allows for a valid split.

**Customer's response:** Fixed in commit [fedf838](#)

**Fix Review:** Fixed

## I-05. Pausing not used inside Restaker

**Description:** The EtherFiRestaker contract implements `pauseContract` and `unPauseContract` and inherits `PausableUpgradeable`. However, no functions in the contract utilize the `whenNotPaused` modifier. This means that calling `pauseContract` has no effect on the contract's operations, potentially giving admins a false sense of security during an emergency.

**Recommendation:** Apply the `whenNotPaused` modifier to critical state-changing functions.

**Customer's response:** Acknowledged – *"All functions are access controlled. Only transferStETH function is called by RedemptionManager which has a pausable modifier used."*

**Fix Review:** Acknowledged

## I-06. Unused code

**Description:** Throughout the codebase there are lines of code that are redundant, because they are not used anywhere:

- EtherFiRestaker - Inside the `stEthClaimWithdrawals`, the first line that reads the ETH balance - [link](#)
- MembershipManager - Inside `migrateFromVOToV1` the final call to `_migrateFromVOToV1` is a redundant, since it was already called in `claim()` before that - [link](#)

**Recommendation:** Remove the redundant lines of code since they are not used anywhere.

**Customer's response:** Fixed in commit [328be4d](#)

**Fix Review:** Fixed – “*The issue is only partially fixed, as the fix has not been applied in the Membership Manager.*”

## I-07. Discrepancy in totalRedeemableAmount() Calculation

**Description:** The `totalRedeemableAmount` function is intended to return the maximum amount of `ETH` (or `stETH`) that can be redeemed at the current moment. This calculation depends on two factors: the rate limit (bucket capacity) and the available liquidity in the pool.

The contract enforces a "low watermark" for liquidity—a minimum buffer that must be preserved. The `canRedeem` function correctly enforces this by checking if the available liquidity above the watermark is sufficient:

```
JavaScript
uint256 availableAmount = liquidEthAmount - lowWatermark;
if (availableAmount < amount) {
    return false;
}
```

However, the `totalRedeemableAmount` function calculates the limit as:

```
JavaScript
return Math.min(consumableAmount, liquidEthAmount);
```

It fails to subtract the `lowWatermark` from `liquidEthAmount`. As a result, it may report a `redeemable` amount that is higher than what is actually allowed by `canRedeem`. If a user or frontend relies on this value to maximize their redemption, the transaction will revert.

**Recommendation:** Update `totalRedeemableAmount` to subtract the low watermark from the liquid amount, ensuring consistency with `canRedeem()`.

**Customer's response:** Fixed in commit [9f9a6ce](#)

**Fix Review:** Fixed

## I-08. Reentrancy in wrapEthForEap can manipulate emitted event values

**Description:** The `wrapEthForEap` function calls `_mintMembershipNFT`, which triggers the `ERC1155 _mint` function. This function invokes `onERC1155Received` on the recipient, passing control back to the caller before the transaction completes.

This allows the recipient to re-enter the membership contract and potentially change the return value of `valueOf()` before the subsequent `_emitNftUpdateEvent` is called.

**Recommendation:** If the event is used by offchain indexers, consider moving the emission before the NFT mint to make sure the value cannot be tampered with

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## I-09. Unfair Dilution in \_topUpDeposit

**Description:** When a user tops up their deposit, if the new total exceeds the penalty threshold, [the contract dilutes](#) their [baseTierPoints](#). The current formula dilutes the points based on the ratio of the entire new deposit to the old deposit.

This means a user topping up just slightly above the threshold suffers a dilution proportional to their entire capital addition, which may be excessively punitive compared to penalizing only the amount exceeding the threshold.

**Recommendation:** Review the dilution formula to ensure it aligns with the intended economic incentives. Consider diluting based only on the "excess" capital (amount above [maxDepositWithoutPenalty](#))

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## I-10. Unused Parameter in deposit function

**Description:** The `deposit(address _user, address _referral)` [function is called](#) by the `MembershipManager` contract. It accepts a `_user` parameter but its value is never used within the function body. The subsequent internal call to `_deposit` credits the minted shares to `msg.sender` (which is the `MembershipManager` contract), not the `_user` address. This can be misleading for developers and integrators reading the code.

**Recommendation:** Remove the unused `_user` parameter from the function signature to improve code clarity and prevent confusion.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## I-11. Redundant State Variable and Function

**Description:** [The contract includes](#) a state variable `restakeBnftDeposits` and a corresponding setter function `setRestakeBnftDeposits`. However, the `restakeBnftDeposits` variable is never read or used anywhere in the contract's logic. This constitutes dead code that adds unnecessary contract size.

**Recommendation:** Remove the `setRestakeBnftDeposits` function

**Customer's response:** Acknowledged – “There are a lot of variables to deprecate in the Liquidity Pool. Will deprecate this one later along with the others.”

**Fix Review:** Acknowledged

## I-12. Mismatch in EigenPod\_validatorPubkeyHashToInfo Implementation

**Description:** The function `EigenPod_validatorPubkeyHashToInfo` is named to suggest it performs a lookup using validator public key hashes. However, its signature accepts full public keys (`bytes[][]`), and its implementation calls `validatorPubkeyToInfo` on the `EigenPod` contract. This logic is identical to the subsequent function `EigenPod_validatorPubkeyToInfo`, making it redundant and misleading.

It appears the intention was for this function to accept bytes32 hashes and query the `validatorPubkeyHashToInfo` mapping directly on the `EigenPod`, which would be more gas-efficient for off-chain viewers that already possess the hashes.

**Recommendation:** Update the function signature to accept `bytes32[][]` memory `_validatorPubkeyHashes` and modify the implementation to call `validatorPubkeyHashToInfo` on the `EigenPod` contract.

**Customer's response:** Fixed in commit [677668d](#)

**Fix Review:** Fixed

### I-13. Inconsistent Access Control Mechanism in EETH

**Description:** Both the `EETH::mintShares` and `EETH::burnShares` functions are restricted to being called only by the liquidity pool contract. However, `mintShares` uses the modifier in order to achieve that, while `burnShares` uses an inline check inside its function body for that, which is unnecessary, given the presence of the `onlyPoolContract` modifier.

**Recommendation:** Consider using the `onlyPoolContract` modifier in both the `mintShares` and `burnShares` functions.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## I-14. Missing Sanity Check in \_handleAccruedRewards

**Description:** In EtherFiAdmin.\_handleAccruedRewards, [the contract calculates](#) the time elapsed since the last report to verify that the APR is within acceptable bounds.

While the protocol logic generally implies that `_report.refSlotTo` should be greater than `lastHandledReportRefSlot`, there is no explicit check enforcing this. If a malformed report were to pass validation where `refSlotTo < lastHandledReportRefSlot`, `elapsedSlots` would be negative, leading to a negative `elapsedTime` and potentially incorrect APR calculations or underflows.

**Recommendation:** Add a sanity check

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## I-15. Unused State Variable in MembershipManager

**Description:** In the current state of the `MembershipManager` contract, the `treasury` state variable isn't being read or used anywhere. This is redundant, adds unnecessary complexity and makes the contract storage bigger than it should be.

**Recommendation:** Consider removing the `treasury` state variable from the `MembershipManager` contract.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## I-16. Redundant Boolean Equation Check

**Description:** In the `processDepositFromEapUser` function of the `MembershipNFT` contract there is the following validation check, that ensures that a given user hasn't yet executed an EAP deposit.

JavaScript

```
function processDepositFromEapUser(address _user, uint32 _eapDepositBlockNumber, uint256  
_snapshotEthAmount, uint256 _points, bytes32[] calldata _merkleProof)  
onlyMembershipManagerContract external {  
    if (eapDepositProcessed[_user] == true) revert InvalidEAPRollover();
```

As it can be seen, the value of the user inside the `eapDepositProcessed` mapping is being taken and then checked whether it's equal to `true` or not. This however is redundant, as boolean values don't need to be checked for being true or false, as this results in a boolean value in itself.

The same redundancy can also be found in `EtherFiOracle.sol#L232;L241;L251` and `RegulationsManager.sol#L68`.

### Recommendation:

Consider simplifying the aforementioned boolean check

JavaScript

```
function processDepositFromEapUser(address _user, uint32 _eapDepositBlockNumber, uint256  
_snapshotEthAmount, uint256 _points, bytes32[] calldata _merkleProof)  
onlyMembershipManagerContract external {  
-    if (eapDepositProcessed[_user] == true) revert InvalidEAPRollover();  
+    if (eapDepositProcessed[_user]) revert InvalidEAPRollover();
```

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## I-17. Incorrect Burn Amount Reported in Event Due to amountForShare Mismatch

**Description:** The `handleRemainder` function in `WithdrawRequestNFT` emits an incorrect amount in the `HandledRemainderOfClaimedWithdrawRequests` event. The event uses `liquidityPool.amountForShare(eEthSharesToBurn)` instead of the actual `eEthAmountToBurn` value. After burning `eEthSharesToBurn`, the value of `eEthSharesToBurn` increases, causing the function to return an amount greater than `eEthAmountToBurn`.

**Recommendation:** Use `eEthAmountToBurn` instead of `liquidityPool.amountForShare(eEthSharesToBurn)`.

**Customer's response:** Fixed in commit [3c6379d](#)

**Fix Review:** Fixed

## I-18. Broken domain separator caching in proxy pattern

**Description:** The `EETH` contract implements a caching mechanism for the `EIP712` domain separator to optimize gas costs, but the cache check is fundamentally broken when the contract is used through a `UUPS` proxy pattern. The contract stores `_CACHED_THIS` in the constructor when the implementation contract is deployed:

However, when the contract is called through a proxy via `delegatecall`, the `address(this)` in the implementation code refers to the proxy's address, not the implementation's address. This creates a permanent mismatch:

- `_CACHED_THIS` = Implementation contract address(set during deployment)
- `address(this)` at runtime = Proxy contract address(when called through proxy)

The cached domain separator(`_CACHED_DOMAIN_SEPARATOR`) is never returned because the condition `address(this) == _CACHED_THIS` always evaluates to false when called through a proxy.

**Recommendation:** Use the proxy address for the caching instead of the implementation contract one

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## I-19. Deposit Cap inconsistency in Liquifier Contract

**Description:** The deposit cap check in [Liquifier](#) uses the `dx` value instead of the original amount. It checks the cap against `dx`(discounted value after discount) instead of the market value (before discount).

- Deposit caps should limit the market value of tokens deposited
- Currently, the code checks the cap against `dx` (discounted value)
- This means deposits can exceed the cap

**Recommendation:** Use market value instead of `dx` when checking for deposit cap.

**Customer's response:** Acknowledged

**Fix Review:** Acknowledged

## Disclaimer

---

Even though we hope this information is helpful, we provide no warranty of any kind, explicit or implied. The contents of this report should not be construed as a complete guarantee that the contract is secure in all dimensions. In no event shall Certora or any of its employees be liable for any claim, damages, or other liability, whether in an action of contract, tort, or otherwise, arising from, out of, or in connection with the results reported here.

## About Certora

---

Certora is a Web3 security company that provides industry-leading formal verification tools and smart contract audits. Certora's flagship security product, Certora Prover, is a unique SaaS product that automatically locates even the most rare & hard-to-find bugs on your smart contracts or mathematically proves their absence. The Certora Prover plugs into your standard deployment pipeline. It is helpful for smart contract developers and security researchers during auditing and bug bounties.

Certora also provides services such as auditing, formal verification projects, and incident response.
